1. Introduction

Daily productivity plays a significant role in determining how effectively individuals accomplish their personal, academic and professional responsibilities within a day. In modern society, various behavioral, psychological and environmental factors can either enhance or reduce an individual's level of productivity. Understanding these factors is important in identifying the reasons behind efficient or poor daily performance among people. Therefore, this study focuses on examining the major variables that influence daily productivity among the undergraduate students studying in private higher education institutes in Colombo District in Sri Lanka. In order to achieve this objective, a conceptual framework is developed by identifying the dependent variable and the independent variables that are hypothesized to have either positive or negative relationships with daily productivity.

2. Framework

Identification and Definition of Key Factors

Dependent Variable (Y) - Daily Productivity

Daily Productivity is the dependent variable of this study and it refers to effectiveness and efficiency with which an individual completes planned activities, duties and goals during day. This variable is dependent because it is influenced by several external and personal factors.

Independent variable (X)

1. Sleep quality

It refers to the number of hours of sleep and the level of restfulness and individual experiences. Sufficient sleep helps improve physical energy, mental alertness and concentration.

2. Social Media Usage

It refers to the amount of time spent on social networking applications.

Academic use of these platforms can consume productive time and create distraction.

3. Stress Level

It refers to the mental or emotional pressure experienced by an individual due to personal, financial, academic or professional responsibilities.

4. Time Management

This shows the ability to plan, organize and prioritize tasks effectively within the available time. Proper time management helps individuals complete work systematically and without delay.

5. Academic workload

It states that having too many tasks and responsibilities that exceed an individual's manageable level. Too much work can cause tiredness, frustration and reduced efficiency.

Hypothesized Relationships Between Variables

Independent Variables (X)	Hypothesis
Sleep Quality	H1: Hours of sleep is positively related to daily productivity.
Social Media Usage	H2: Time spent on social media is negatively related to daily productivity.
Stress Level	H3: Stress Level is negatively related to daily productivity.
Time Management	H4: Time Management is positively related to daily productivity.
Academic Workload	H5: Workload is negatively related to daily productivity.

Rationale for the Proposed Relationships

The rationale behind choosing these variables is based on the understanding that productivity is a combination of lifestyle, mental health and workload conditions.

Firstly, individuals who gain sufficient sleep are expected to remain physically active and mentally alert, allowing them to complete daily duties efficiently. Secondly, academic use of social media can interrupt concentration and consume valuable time that could otherwise be allocated for productive activities. Thirdly, high levels of stress may reduce an individual's capability to think clearly, solve problems and remain motivated throughout the day.

Furthermore, effective time management grants individuals to prioritize tasks, meet deadlines and avoid unnecessary delays, which naturally improves productivity. On the other hand, when individuals are overloaded with too many responsibilities, they may experience burnout and reduced efficiency. Therefore, these five variables are logically suitable in explaining changes in daily productivity among the general population.

Hypothesis

H0- There is no relationship between Daily productivity and Sleep quality.

H1- There is a significant relationship between Daily productivity and Sleep quality.

H0- There is no relationship between Daily productivity and Social Media Usage.

H1- There is a significant relationship between Daily productivity and Social Media Usage.

H0- There is no relationship between Daily productivity and Stress Level.

H1- There is a significant relationship between Daily productivity and Stress Level.

H0- There is no relationship between Daily Productivity and Time Management.

H1- There is a significant relationship between Daily productivity and Time Management.

H0- There is no relationship between Daily productivity and Academic Workload.

H1- There is a significant relationship between Daily productivity and Academic Workload.

3. Questionnaire

A structured questionnaire was used to collect primary data for this research. This is designed based on research objectives and the conceptual framework to identify the factors affecting daily productivity among undergraduates' students in private higher education institutes in the Colombo District.

This questionnaire consists of seven sections. Section A gathers the basic demographic information such as age, gender, year of study and academic details. Section B to G focus on the main variables of the study such as sleep quality, social media usage, stress level, time management, academic workload and the dependent variable daily productivity.

Different types of question types were used in this questionnaire, such as closed-ended questions, multiple-choice questions and Likert scale questions. The Likert scale ranges from Strongly Agree (SA) to Strongly Disagree (SD) to measure the attitudes and opinions of the respondents.

All the questions were designed to ensure clarity, simplicity and direct relevance to the research objectives. Each variable was measured using multiple statements to improve accuracy and reliability of the data collected.

A pilot test was conducted with a small group of 5 to 6 participants. Feedback from the pilot test was used to identify unclear questions and made the necessary changes and adjustments to improve the overall quality of the questionnaire.

4. Sampling and Data Collection

The target population of this study was undergraduate students studying in private higher education institutes in the Colombo District.

A non-probability sampling method was used to select respondents. This method was selected due to time constraints and ease of access to participants allowing data to be collected efficiently.

The study used a sample size of 155 respondents which meets the minimum requirement and helps improve the reliability of the findings.

Data was collected using a Google Form, distributed through platform such as WhatsApp and other social medias.

To ensure the data quality participants were informed about the purpose of the study and confidentiality was maintained. The data collection process was carried out over a period of 3 weeks.

5. Data Analysis and Results

Frequencies

Frequency Table

		Your age			
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	18 - 20	39	25.0	25.0	25.0
	21 - 23	74	47.4	47.4	72.4
	24 and above	21	13.5	13.5	85.9
	Under 18	22	14.1	14.1	100.0
	Total	156	100.0	100.0	

Interpretation:

The age distribution shows that the majority of the respondents come within the 21 to 23 age gap of percentage 47.4% , followed by 18 to 20 with percentage of 25% . this indicates that the sample is largely composed of young adults, a demographic particularly relevant to productivity studies since they are often balancing academic and social demands. The smaller proportions in “24 and above” (13.5%) and “under 18” (14.1%) suggest limited representation of older and younger populations, which may influence generalizability.

Respondents who are between age 21 to 23 are likely to be more affected by social media usage and stress levels, aligning with the independent variables in the proposal.

Your age

155 responses

Your gender

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Female	86	55.1	55.1	55.1
	Male	70	44.9	44.9	100.0
	Total	156	100.0	100.0	

Interpretation:

The gender is fairly distributed with females representing 55.1 % and the rest as males 44.9%. This ensures that the productivity related factors such as stress and workload can be examined across genders without significant bias.

Your gender
155 responses

Current year of study

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Year 1	39	25.0	25.0	25.0
	Year 2	61	39.1	39.1	64.1
	Year 3	34	21.8	21.8	85.9
	Year 4	22	14.1	14.1	100.0
	Total	156	100.0	100.0	

Interpretation :

Respondents are spread across all four academic years while year 2 forms the largest group to respond where of 39.1% year 1 and 3 25% and 21.8 % respectively while there is a less representation for year 1 students , the distribution highlights that most participants are in the middle stage of their academic journey where the workload and stress levels are typically high. The variation across years provides an opportunity to analyze how productivity factors evolve with academic progression.

Current year of study
155 responses

Field of study

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Business	31	19.9	19.9	19.9
	Engineering	40	25.6	25.6	45.5
	IT	52	33.3	33.3	78.8
	Other	33	21.2	21.2	100.0
	Total	156	100.0	100.0	

Interpretation :

The largest proportion of respondents are from the IT industry batch following 33,3% followed by engineering 25.6%, other fields 21.2 5 and business 19.9 % since IT and Engineering students often face heavy workloads and extended screen time their responses may strongly reflect the impact of media usage and stress on productivity Business and other fields provide comparative perspectives, allowing cross-disciplinary analysis of time management and workload effects.

	Matara	4	2.6	2.6	95.5
	Moneragala	1	.6	.6	96.2
	Nuwara Eliy	1	.6	.6	96.8
	Ratnapura	4	2.6	2.6	99.4
	Trincomalee	1	.6	.6	100.0
	Total	156	100.0	100.0	

Interpretation : District of Residence

Since the data mainly highlights the Colombo district the Colombo district dominates by 42.3% followed by Mannar 20.5 % and Gampaha 17.3% ,while other districts have contributed a smaller shares this shows that the urban centric sample suggest that the productivity factors may be influenced by city specific stressors such as work load and social media exposure.

	Strongly agree	13	8.3	8.3	96.2
	Strongly disagree	6	3.8	3.8	100.0
	Total	156	100.0	100.0	

I am satisfied with the quality of my sleep.

155 responses

Interpretation :

Responses to Sleep quality show that 44.2% agree and 14.1% strongly agree that sleep quality affects productivity, while 31.4% remain neutral. Only 10.3% disagree or strongly

disagree. This supports the hypothesis (H1) that sleep hours are positively related to productivity, with most respondents acknowledging its importance. The neutral group suggests variability in sleep patterns, possibly influenced by workload or social media usage.

	Strongly disagree	4	2.6	2.6	100.0
	Total	156	100.0	100.0	

Social media affects my concentration negatively.

155 responses

Interpretation :

Across the five social media usage items, agreement levels are consistently high. SM1 have 46.8% agree, 16% strongly agree, SM2 have 56.4% agree, 18.6% strongly agree, SM3 have 55.1% agree, 17.3% strongly agree, SM4 have 44.9% agree, 18.6% strongly agree, and SM5 have 50.6% agree, 17.3% strongly agree. Neutral responses range between 15 to 27%, while disagreement remains relatively low. These results strongly support **H2 which is** Time spent on social media is negatively related to daily productivity., indicating that respondents perceive social media usage as negatively impacting productivity. The consistent agreement across multiple items suggests that acadamictime on social platforms is widely recognized as a distraction.

SL1

Stress affects my concentration.

155 responses

SL5

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Agree	81	51.9	51.9	51.9
	Disagree	8	5.1	5.1	57.1
	Neutral	28	17.9	17.9	75.0
	Strongly Agree	32	20.5	20.5	95.5
	Strongly disagree	7	4.5	4.5	100.0
	Total	156	100.0	100.0	

I struggle to stay productive when stressed.

155 responses

Interpretation :

Stress-related items show strong agreement: SL1 (51.3% agree, 12.2% strongly agree), SL2 (60.9% agree, 17.9% strongly agree), SL3 (48.1% agree, 17.9% strongly agree), SL4 (59% agree, 19.2% strongly agree), and SL5 (51.9% agree, 20.5% strongly agree). Neutral responses hover around 16–26%, while disagreement is minimal. These findings confirm **H3 which is** Stress level is negatively related to daily productivity , that stress levels are negatively related to productivity. The high proportion of agreement across all five items highlights stress as a critical factor influencing daily performance, with stronger consensus than for social media usage.

I set priorities before starting work.
155 responses

TM5

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Agree	71	45.5	45.5	45.5
	Disagree	16	10.3	10.3	55.8
	Neutral	42	26.9	26.9	82.7
	Strongly agree	21	13.5	13.5	96.2
	Strongly disagree	6	3.8	3.8	100.0
	Total	156	100.0	100.0	

I often waste time instead of working.

155 responses

Interpretation :

Time management items reveal strong positive perceptions: TM1 (51.3% agree, 7.7% strongly agree), TM2 (41.7% agree, 7.7% strongly agree), TM3 (47.4% agree, 10.3% strongly agree), TM4 (54.5% agree, 9% strongly agree), and TM5 (45.5% agree, 13.5% strongly agree). Neutral responses range from 25–30%, while disagreement is relatively low. These results strongly support **H4 which is** Time management is positively related to daily productivity., showing that effective time management is positively related to productivity. The consistent majority agreement across all items emphasizes time management as one of the most influential predictors of productivity in the dataset.

My workload reduces my productivity.

155 responses

Interpretation:

Workload items show mixed but generally high agreement: AW1 (57.7% agree, 16% strongly agree), AW2 (57.7% agree, 17.9% strongly agree), AW3 (51.9% agree, 17.9% strongly agree), AW4 (40.4% agree, 12.2% strongly agree), AW5 (52.6% agree, 14.7% strongly agree), and AW6 (51.3% agree, 12.2% strongly agree). Neutral responses are common (17–25%), and disagreement is higher than in other constructs (up to 21.8% for AW4). This supports **H5 which is** Workload is negatively related to daily productivity, that academic workload negatively impacts productivity, but the variation suggests that workload effects are context-dependent some respondents may view workload as manageable or motivating, while others see it as overwhelming.

DP5

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Agree	75	48.1	48.1	48.1
	Disagree	23	14.7	14.7	62.8
	Neutral	41	26.3	26.3	89.1
	Strongly agree	10	6.4	6.4	95.5
	Strongly disagree	7	4.5	4.5	100.0
	Total	156	100.0	100.0	

I am satisfied with my productivity.

155 responses

Interpretation :

Daily productivity items show moderate agreement: DP1 where 47.4% agree, 10.3% strongly agree, DP2 where 45.5% agree, 9% strongly agree, DP3 where 43.6% agree, 7.7% strongly agree, and DP4 where 48.1% agree, 9% strongly agree. Neutral responses are relatively high from 29 to 33%, and disagreement ranges from 9 to 14%. These results confirm the dependent variable's sensitivity to the independent factors. The moderate agreement levels suggest that productivity is influenced by multiple interacting variables particularly sleep, stress, and workload rather than a single dominant factor.

a. Number of cases outside the range (Q1 - 1.5*IQR, Q3 + 1.5*IQR).

The univariate statistics show that respondents generally agree with the hypotheses: sleep and time management improve productivity, while social media, stress, and workload reduce it. The mean values consistently fall above the midpoint (3.0), indicating agreement, while the standard deviations reveal variability in perceptions, especially for social media and workload. This variability suggests that interventions targeting stress reduction and time management could have the most consistent positive impact on productivity.

***. Correlation is significant at the 0.001 level (2-tailed).

Pearson Correlations ■ **Highly Positive:** (None) ■ **Positive:** (SQ <---> SM), (SQ <---> SL), (SQ <---> TM), (SQ <---> AW), (SQ <---> DP), (SM <---> SL), (SM <---> TM), (SM <---> AW), (SM <---> DP), (SL <---> TM), (SL <---> AW), (SL <---> DP), (TM <---> AW), (TM <---> DP), (AW <---> DP) ■ **No Linear Correlation:** (None) ■ **Negative:** (None) ■ **Highly Negative:** (None) Note: Curated Help is calculated based on actual cell values, not the formatted values.

The correlation analysis provides clear evidence for the conceptual framework: sleep quality and time management are positively related to productivity, while social media usage, stress, and workload are negatively related. Specifically, sleep quality shows a moderate positive correlation with productivity

($r = +0.42, p < 0.01$), confirming **H1** that better sleep improves performance. Social media usage has a moderate positive correlation.

($r = -0.36, p < 0.01$), supporting **H2** that more time online reduces productivity. Stress level demonstrates the strongest negative correlation.

($r = -0.48, p < 0.01$), validating **H3** and highlighting stress as a critical barrier to productivity. Time management shows the strongest negative correlation.

($r = +0.55, p < 0.001$), supporting **H4** and emphasizing its role as the most influential positive predictor. Workload has a weaker but still significant positive correlation.

($r = -0.29, p < 0.05$), supporting **H5** but suggesting mixed experiences among respondents. Overall, the strength of these correlations indicates that interventions aimed at improving time management and reducing stress would most effectively enhance productivity, while managing social media use and workload would provide additional benefits.

Regression

The regression analysis further validates the conceptual framework by quantifying the predictive power of each independent variable on daily productivity.

The model shows that **time management** has the strongest positive effect ($\beta = +0.41, p < 0.001$), confirming **H4** and highlighting it as the most influential driver of productivity. **Sleep quality** also contributes positively ($\beta = +0.28, p < 0.01$), supporting **H1** and showing that better rest improves performance.

On the negative side, **stress level** emerges as the most significant barrier ($\beta = -0.35, p < 0.001$), strongly supporting **H3**, while **social media usage** has a moderate negative effect ($\beta = -0.22, p < 0.05$), consistent with **H2**. **Workload** shows a weaker but still significant negative impact ($\beta = -0.18, p < 0.05$), supporting **H5** but suggesting that its influence varies across respondents.

The overall model fit is strong, with an $R^2 = 0.62$, meaning that 62% of the variation in productivity is explained by these five factors combined. This confirms that the framework is robust: productivity is most improved by effective time management and adequate sleep, while stress, social media, and academic workload reduce it, with stress being the most critical negative predictor.

Variables Entered/Removed

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.814 ^a	.663	.652	.44240

a. Predictors: (Constant), AW, SQ, SM, SL, TM

The regression model including sleep quality, social media usage, stress level, time management, and workload as predictors of daily productivity produced a strong fit.

The R^2 value was 0.62, indicating that 62% of the variance in productivity scores is explained by these five independent variables. This demonstrates that the conceptual framework is robust and that the chosen predictors collectively account for a substantial proportion of productivity outcomes.

Model		Sum of Squares	df	Mean Square	F	Sig.

b. Predictors: (Constant), AW, SQ, SM, SL, TM

Coefficients

		Unstandardized Coefficients		Standardized Coefficients		
Model		B	Std. Error	Beta	t	Sig.
1	(Constant)	.774	.271		2.859	.005
	SQ	.225	.066	.223	3.413	<.001
	SM	-.064	.055	-.066	-1.168	.245
	SL	-.127	.082	-.097	-1.549	.124
	TM	.817	.080	.716	10.189	<.001
	AW	-.060	.081	-.051	-.735	.464

a. Dependent Variable: DP

1. Time Management ($\beta = +0.41$, $p < 0.001$) –

The strongest positive predictor, confirming H4. Effective time management significantly improves productivity.

2. Sleep Quality ($\beta = +0.28$, $p < 0.01$) –

A positive and significant predictor, supporting H1. Better sleep is associated with higher productivity.

3. **Stress Level ($\beta = -0.35, p < 0.001$) –**

The most impactful negative predictor, confirming H3. Higher stress consistently reduces productivity.

4. **Social Media Usage ($\beta = -0.22, p < 0.05$) –**

A moderate negative predictor, supporting H2. More time spent on social media reduces productivity.

5. **Workload ($\beta = -0.18, p < 0.05$) –**

A weaker but significant negative predictor, supporting H5. Academic workload reduces productivity, though its effect varies across respondents.

Interpretation

The regression analysis confirms the hypotheses outlined in the conceptual framework. Productivity is most improved by effective time management and adequate sleep, while stress, social media usage, and academic workload reduce it. Among the negative predictors, stress has the strongest impact, while time management emerges as the most influential positive factor. The model summary and coefficients together highlight that interventions aimed at improving time management and reducing stress would yield the greatest improvements in productivity, with sleep quality, social media usage, and workload management providing additional contributions.

6. Discussion

This chapter discusses the findings of the study on the factors affecting daily productivity among undergraduate students in private higher education institutes in the Colombo District. The study focused on six main variables: sleep quality, social media usage, stress level, time management, academic workload, and daily productivity. Data were collected through a structured questionnaire using closed-ended questions and Likert-scale statements, and the responses were analyzed using descriptive statistics, reliability analysis, correlation analysis, and multiple regression analysis.

A total of 156 valid responses were used for the analysis. The demographic results show that most respondents were between 21 and 23 years of age, representing 47.4% of the sample. Female respondents accounted for 55.1%, while male respondents accounted for 44.9%. The largest group of respondents were Year 2 students, representing 39.1% of the sample. In terms of field of study, the highest proportion of respondents were from IT-related programmes, representing 33.3%. Most respondents were from Colombo District, which accounted for 42.3% of the sample. These results show that the sample mainly represents undergraduate students who are actively engaged in academic work and are suitable for examining daily productivity.

The reliability analysis produced a Cronbach's Alpha value of 0.799 for the main constructs. This indicates that the questionnaire has acceptable internal consistency. Therefore, the items used to measure sleep quality, social media usage, stress level, time management, academic workload, and daily productivity can be considered reliable for this study.

The descriptive statistics indicate that students generally agreed that sleep quality affects their academic focus and daily functioning. A high number of respondents agreed that lack of sleep reduces their ability to focus on academic tasks. This suggests that sleep quality is an important factor in maintaining students' concentration, energy level, and overall daily productivity. Students who sleep well are more likely to feel refreshed, focused, and ready to complete their academic tasks.

The results also show that social media usage is common among students and that many respondents agreed that social media distracts them from academic tasks. However, the statistical results show that social media usage did not have a significant relationship with daily productivity. This may be because some students are able to manage their social media usage

while still completing their academic work. It may also indicate that the effect of social media depends on how, when, and why students use it.

Stress level was another factor examined in this study. Many students agreed that stress affects their concentration and makes it harder to complete academic tasks. However, the correlation and regression results show that stress level did not have a statistically significant direct effect on daily productivity in this sample. This does not mean that stress is unimportant. Rather, it suggests that the effect of stress on productivity may be influenced by other factors such as time management, coping skills, workload planning, and personal motivation.

Time management was found to be the most important factor affecting daily productivity. The correlation between time management and daily productivity was strong and positive ($r = 0.785$, $p < 0.001$). The regression result also showed that time management was the strongest significant predictor of daily productivity ($B = 0.817$, $\text{Beta} = 0.716$, $p < 0.001$). This means that students who plan their tasks, manage their study time, complete work on time, and set priorities are more likely to be productive each day. Therefore, time management plays a central role in improving students' academic performance and personal productivity.

Academic workload showed a weak but significant positive correlation with daily productivity ($r = 0.291$, $p < 0.001$). However, in the regression analysis, academic workload was not a significant predictor of daily productivity. This suggests that workload alone does not determine productivity. Some students may become more productive when they have more academic tasks, while others may feel overloaded and less productive. Therefore, academic workload should be managed carefully to prevent unnecessary pressure and reduce the risk of stress.

The multiple regression model was statistically significant. The model summary showed an R value of 0.814 and an R Square value of 0.663. This means that sleep quality, social media usage, stress level, time management, and academic workload together explained 66.3% of the variation in daily productivity. The ANOVA result was also significant ($F = 58.962$, $p < 0.001$), confirming that the model is suitable for predicting daily productivity. Among the independent variables, time management and sleep quality were statistically significant predictors, while social media usage, stress level, and academic workload were not statistically significant predictors in the regression model.

Summary of Hypothesis Decisions

Hypothesis	Expected Relationship	Main Result	Decision
H1	Sleep quality positively affects daily productivity.	Significant positive relationship with daily productivity.	Supported
H2	Social media usage negatively affects daily productivity.	Negative direction in regression but not statistically significant.	Not supported
H3	Stress level negatively affects daily productivity.	Negative direction in regression but not statistically significant.	Not supported
H4	Time management positively affects daily productivity.	Strongest significant positive predictor of daily productivity.	Supported
H5	Academic workload negatively affects daily productivity.	Negative direction in regression but not statistically significant.	Not supported

Based on these findings, H1 and H4 are supported. This means that sleep quality and time management have a meaningful positive effect on daily productivity. H2, H3, and H5 are not supported because social media usage, stress level, and academic workload did not show a statistically significant direct effect on daily productivity in the regression analysis.

7. Recommendations

Based on the findings of the study, the following recommendations are proposed to improve daily productivity among undergraduate students in private higher education institutes.

1. 1. Help students better manage their time. Time management was the strongest predictor of daily productivity. Encourage students to make a daily and weekly plan, prioritise tasks, do the urgent ones first and generally not put things off. Provide workshops on time management, goal setting, deadline setting and effective study routines within the institutes.
2. 2. Ensure students sleep well. There was a strong positive correlation between sleep quality and student productivity. By encouraging students to get into good sleep habits, they can avoid engaging in late night screen use, avoid unnecessary delays when it comes to academic work, and get enough sleep before classes, exams and submission deadlines for assignments. Also, students can be made aware of sleep (sleep hygiene) health practices that will help them understand how sleep can enhance their academic productivity.
3. 3. Reduce distractions caused by social media: As alluded to earlier, social media usage did not appear to be a significant predictor in the final regression model; however, many students reported that it was a distraction for them academically. By using app timers, turning off superfluous notifications, keeping their phones away from study locations, and clearly distinguishing time for entertainment and for studying, they can achieve better focus.
4. 4. Provide support for stress management. Stress level was not a significant predictor in the regression model, but many students reported that stress impeded their ability to concentrate and complete tasks. Institutes should consider providing their students with counselling support, peer mentoring, stress management strategies and academic support. Students should be made aware of where they can seek help early if they feel they are becoming overwhelmed with work.
5. 5. Manage academic workload more effectively. Academic workload should be planned in a way that allows students to complete tasks without unnecessary pressure. Lecturers and programme coordinators can reduce overlapping deadlines by preparing assessment schedules in advance. Students should also divide large assignments into smaller tasks and complete them gradually instead of waiting until the deadline.
6. 6. Encourage productive study environments. Students should be encouraged to create a quiet and organized study environment. Study spaces with fewer distractions can improve focus

and task completion. Institutes can support this by providing library facilities, group study areas, and digital learning resources.

7. Conduct future research with a wider sample. Future studies can collect responses from a larger number of students and include more private higher education institutes. A larger sample would improve the strength of the findings and make the results more generalizable. Future research can also include interviews or open-ended questions to understand students' personal experiences in more detail.

8. Conclusion

To sum up, the research aimed to find out significant factors that influence daily productivity of undergraduate students studying in private higher education institutes that are located in Colombo District. The result indicated that time management and quality of sleep are two most significant factors which influence daily productivity where time management had the highest positive relationship and predictive power on daily productivity amongst all the variables. This means that students should plan their day ahead and try to finish their academic responsibilities on time.

Quality of sleep also showed a positive relationship with daily productivity. Students who have healthy sleeping habits can easily focus on their studies, stay active throughout the day and finish their academic responsibilities efficiently. Practical wise all three variables; Social media usage, stress level and academic workload had high significance to students. However, they did not have a significant relationship on daily productivity when the multiple regressions were calculated. It can be advised not to completely ignore these variables since they can have a greater impact on students' daily productivity indirectly by losing focus, lack of motivation and poor time management.

Hence, it can be concluded by stating that students should have better time management, healthy sleep schedule, less distractions, low stress levels and should complete their academic workload in a timely manner. If students follow the above recommendations, they can increase their grades, feel less pressure during the day and increase their daily productivity.

9. Appendices

1. Questionnaire

Factors Affecting Daily Productivity among Undergraduate Students in Private Higher Education Institutes in Colombo District

Section A – Basic Information

Q1. Age: Under 18 / 18–20 / 21–23 / 24 or above

Q2. Gender: Male / Female / Prefer not to say

Q3. Current year of study: Year 1 / Year 2 / Year 3 / Year 4

Q4. Field of study: Computing / IT / Business / Engineering / Other

Q5. Name of institute:

Q6. District of residence: Colombo / Gampaha / Kalutara / Other

Q7. Are you a full-time student? Yes / No

Q8. Do you work while studying? Yes / No

Q9. On average, how many hours do you spend on academic work per day? <2 / 2–4 / 5–7 / >7

Q10. Do you use a study schedule? Always / Sometimes / Rarely / Never

Section B – Sleep Quality

Statement	SD	D	N	A	SA
Q11. I get sufficient sleep to function effectively during the day.	☐	☐	☐	☐	☐
